CHS Multi-Platform Deployment

CHS — Multi-Platform Deployment: The Real, Current Answer

The direct answer first

CHS can genuinely be installed on a PC, a tablet, an Android phone, and an iPhone today — right now, with nothing further to build. I checked the actual code directly to confirm this, not from memory.

What's actually already built and working

CHS is a real Progressive Web App (PWA). Three things are required for a website to become a genuinely installable app, and all three are confirmed present and correctly configured:

1. **A real app manifest** — tells the phone or computer the app's name, icon, and colors, and that it should open full-screen like a real app, not a browser tab.
2. **A real service worker** — lets the app keep working and feel fast even on a poor connection.
3. **Real icon files**, at the correct sizes, already in place.

How someone actually installs it today, on each device

On a PC or laptop (Chrome or Edge): open the CHS website, and a real "Install" icon appears in the browser's address bar. One click installs it as a genuine, standalone desktop app — its own window, its own icon in the Start Menu or Dock, no browser bar showing.

On an Android phone: open the site in Chrome, tap the menu, and choose "Install app" (or Chrome may offer this automatically). It installs a real icon on the home screen that opens full-screen.

On an iPhone (Safari): open the site, tap the Share icon, then "Add to Home Screen." iOS handles a few things slightly differently than Android under the hood, but the real result is the same — a genuine home-screen icon that opens full-screen.

None of this requires the Apple App Store or Google Play Store. This is a real, complete, working path to being on every device, available immediately.

What a real App Store / Play Store *listing* would additionally require

This is a genuinely separate, real piece of work — not a natural next step of what already exists, and not something to treat as a quick add-on:

- **Apple App Store:** a paid Apple Developer account ($99/year), and — since Apple does not accept a plain website as an app submission — the PWA needs to be wrapped in a minimal native shell (a real, standard, well-understood process) before submission. Apple's review process typically takes a few days and can request changes.
- **Google Play Store:** a one-time $25 developer account, and a similar real packaging step (Android has better native PWA support than iOS, so this step is usually simpler). Google's review is generally faster than Apple's.

My honest, direct recommendation

Since the real, working installable version already exists on every device today, I don't think app-store listings are something to hold the launch on. The genuine value of an app-store listing is **discoverability** — people browsing the App Store or Play Store specifically looking for a housing app — not functionality, since the app already works identically either way. I'd treat this as a real, worthwhile piece of marketing work to plan for *after* launch, once there's a genuine reason to invest in it (like a marketing push), rather than a blocker before going live.
