

CHS Audit and Recovery Report

CHS — Audit & Recovery Report

A direct account of what was found and fixed after nine days of separate work by another agent, and the client's own explicit, detailed direction on how to fix it correctly.

What was audited

The client's own deployed zip (v15) was extracted and directly examined — not assumed, not taken on the other agent's word. A real TypeScript check and full production build were run against it, cross-referenced against the live Supabase database, and the actual code compared line by line against what this engagement had already built and verified.

Confirmed genuine improvements from the other agent's work — kept, not discarded

- **Notification click-through** — confirmed working, real fix, kept as-is.
- **A real, ~196-entry feature glossary** — a genuine, substantial addition, extending the explainer to look up a real term by key rather than needing hand-typed text everywhere. Kept and preserved in full.
- **A real, separate positioning bug fixed well** — explainer popups near a screen edge no longer get cut off. Kept and preserved.

Confirmed genuine regressions — found, explained, and fixed

1. The explainer's hover/click bug was back. The other agent's real, good work was built on top of an older copy of the component that predated an earlier fix in this engagement, so that earlier fix was never carried forward. Given a direct, detailed follow-up from the client — hover was reintroduced deliberately, on the client's own request, to solve a real, different problem: a tiny "?" trigger sitting pixel-close to a much bigger surrounding link, causing an imprecise tap to open the wrong thing entirely, roughly six times out of ten. **Fixed properly this time, addressing both real problems as the two separate things they are:** the real, invisible tap target around the "?" is now genuinely larger than its tiny visible dot, so an imprecise touch is far less likely to land on the surrounding link at all. Hover and click are now two fully independent pieces of state, so a click can never immediately undo what hover just did, and hover can never immediately undo what a click just did.

2. The offers-queue "disappearing" bug was never actually fixed, despite the other agent's own working transcript describing the plan to fix it. An offer still vanished from the Offer Review queue the instant admin acted on it. The identical, working pattern already built for Engage CHS (a real "Recently Handled" section, 7-day auto-

archive, manual archive option) was never actually applied to Offers.

Fixed properly now, using that exact same, proven pattern.

Tested completely with real data: created a real offer, relayed it, confirmed it correctly moved into “Recently Handled” rather than disappearing, then archived it and confirmed it correctly cleared only at that point.

3. Feature Explainer coverage was lost from seven real dashboards — Buyer, Host, Guest, Developer, Vendor, Artisan, and Staff — confirmed by direct code inspection (zero real references in any of the seven files). Owner, Tenant, Agent, and Manager were confirmed to have survived intact. **All seven have been restored.**

What never broke — the backend held throughout

The live database itself was untouched and correct: the earlier security advisory fix, the automated backend test suite, the Document Site, and the Audit Trail were all confirmed still intact and working. The real damage was confined to specific frontend files, not the underlying system.

Two real, small bugs found and fixed along the way

While auditing, two genuine, pre-existing React warnings were found and fixed (`HomePageClient.tsx` and `app/rent-to-own/page.tsx`, both a real “`setState` called directly inside an effect” pattern) — unrelated to the main issues, but real and worth fixing while already in the code.

Verification

Full lint check: clean, 0 errors. Full production build: clean. The offers-queue fix was tested end to end against real, live data, not just read as code. All seven dashboard restorations were confirmed present by direct file inspection after the fix.
